Range extension for, and description of the juvenile of, Bicoloured Antvireo *Dysithamnus occidentalis punctitectus* in Ecuador

Ana Ágreda, Jonas Nilsson, Luis Tonato and Hernando Román

*Cotinga* 24 (2005): 20–21

Bicoloured Antvireo *Dysithamnus occidentalis* is a rare bird with a scattered distribution from southwest Colombia to east Ecuador\(^1\),\(^4\), and has recently been discovered in north-east Peru (D. Lane pers. comm.). The species’ populations are apparently small and isolated, and there is some variation in morphological and vocal characters between populations\(^2\). Consequently, the species’ taxonomy is unclear. Pacific-slope populations in Colombia belong to nominate *occidentalis*, which is known from four localities and five specimens, including the type, collected at El Cocal at 1,200 m\(^1\). In Ecuador, *D. o. punctitectus* is distributed east of the Andes, but a female presumed to be of nominate *occidentalis* was observed and tape-recorded on the west slope, at Reserva Cerro Golondrina (2,200 m), Carchi province\(^2\). The five specimens from the type, collected at El Cocal at 1,200 m\(^1\), and currently deposited at MECN (8211), was mist-netted on 8 March within dense 2–3 m-high understorey inside riparian forest. It weighed 21.2 g. Mensural data from this specimen were compared with the adults deposited at MECN (Table 1). Wing chord was measured from the bend of the closed wing to the tip of the longest primary, the culmen \((1)\) from the tip of the bill to the forehead, and alternatively culmen \((3)\) as from the tip of the bill to the distal part of the nostril, the longest rectrix from the body to the tip, and tarsus from the rear middle of the intertarsal joint to the distal edge of the last complete scale or the end of tarsal bone\(^6\). The specimen exhibited some body moult but none in the primaries. Age was determined by skull ossification and presence of bursa. Skull ossification was estimated as 40% and the whitish bursa measured 4.5 mm in diameter. The bill was a male having inconspicuous whitish testes of 1.9 mm. Soft-part colours (noted prior to preparation) were as follows: irides dark grey, tarsus dark grey and bill mainly black with a yellowish gape. Stomach content consisted of the remains of insects, but specific identification proved impossible.

Although the specimen was sexed as a male, it more closely resembled a female in plumage characters. It has a dark brown, almost rufescent, crown and forehead, and greyish nape. The
upperparts, mantle and tail are primarily sooty grey with some rufous-brown feathering. The head-sides are dark grey with unstreaked throat-sides. The throat, breast and upper belly are uniform slate grey, slightly darker on the breast, but the flanks and lower belly are chestnut. Two distinct lines of round whitish terminal spots are present on the median and greater wing-coverts, and a conspicuous white patch on the innermost lesser wing-coverts. The fringes of the primaries and secondaries, as well as of the marginal-coverts, are chestnut. There is no concealed dorsal patch (contra Ridgely & Tudor3 and Ridgely & Greenfield4), as in adults at MECN, which also lack such a character. In contrast to the adult female deposited at MECN, which also lack such a character. These specimens are smaller than Bicoloured Antvireo and, in contrast to the latter, exhibit whitish streaks on the head-sides and body. The presence of both species at the same locality and elevation is apparently indicative of the good forest state at this locality.

Field observations
On 10 March at c.17h30 and at an elevation of 1,850 m, JN briefly observed two parties of Bicoloured Antvireos. The first comprised a male, female and at least one additional, unsexed individual. The birds foraged rapidly 2–5 m above ground in the undergrowth, inspecting dead leaves and twigs within stands of vegetation interspersed by treefalls and open undergrowth. They were generally quiet, but vocalisations were described as a soft puh-puh, puh, as well as a faster rolling tcheuw-uw-uw-uw, tcheuw-uw-uw-uw-uw-uw. These birds foraging in mixed-species flocks containing Pearled Treerunner Margarornis squamiger, Sepia-brown Wren Cinnycerthia olivacea and Russet-crowned Warbler Basileuterus coronatus. This observation differs from previous foraging behaviour, described by Whitney7, who observed the species primarily in pairs or alone, but did not reject the potential for participation in mixed-species flocks, as known for congeners.

In the same area we collected, and tape-recorded the natural vocalisations, of White-streaked Antvireo Dysithamnus leucostictus, representing the first records on the west side of the Cordillera del Cóndor in Ecuador (the first records in this region are from Comainas5). The specimens are an adult male and juvenile male, which (much as the Bicoloured Antvireo described above) resembled a female in plumage characters. These specimens are smaller than Bicoloured Antvireo and, in contrast to the latter, exhibit whitish streaks on the head-sides and body. The presence of both species at the same locality and elevation is apparently indicative of the good forest state at this locality.
